2. Break Down the Problem into Smaller Parts

- Decompose complex questions into manageable sub-problems.
- Focus on deriving specific quantities step-by-step (e.g., partition function first, then other thermodynamic variables).

3. Recall Relevant Theoretical Frameworks

- Review fundamental formulas and their derivations from Pathria's text or other trusted sources.
- Identify the appropriate probability distribution or statistical model.

4. Use Mathematical Tools Effectively

- Apply integrals, summations, and approximation techniques where necessary.
- Utilize known identities and properties of functions (e.g., Bose-Einstein, Fermi-Dirac integrals).
- Check the limits of integrals and sums for physical consistency.

5. Verify Results and Consistency

- Ensure units are consistent throughout calculations.
- Compare derived results with known special cases or limiting behaviors.
- Cross-validate calculations by different methods if possible.

Step-by-Step Solutions to Common Pathria Statistical Problems

Let's walk through some typical problems to illustrate how to apply these strategies effectively.

Example 1: Calculating the Partition Function for a Classical Gas

Problem: Find the partition function Z for a monatomic ideal gas of N particles in a

three-dimensional box of volume (V) at temperature (T) .

Solution:

- **Identify the ensemble:** Canonical ensemble, since temperature (T) , number of particles (N) , and volume (V) are fixed.

- **Write down the single-particle partition function (z) :**

[

$$z = \frac{1}{h^3} \int e^{-\beta \frac{p^2}{2m}} d^3p \int d^3q$$

]

where $(\beta = 1/(k_B T))$, (h) is Planck's constant, (p) is momentum, and (q) is position.

- **Perform the integrals:** The spatial integral yields volume (V) , and the momentum integral yields:

[

$$\int e^{-\beta p^2 / 2m} d^3p = (2\pi m k_B T)^{3/2}$$

]

Therefore,

[

$$z = \frac{V}{h^3} (2\pi m k_B T)^{3/2}$$

]

- **Calculate the total partition function (Z) :** For (N) distinguishable particles,

[

$$Z = \frac{z^N}{N!}$$

]

Using Stirling's approximation for large (N) . This accounts for quantum indistinguishability if needed.

Result:

$$Z = \frac{1}{N!} \left[\frac{V}{h^3} (2\pi m k_B T)^{3/2} \right]^N$$

This partition function forms the basis for deriving thermodynamic properties like internal energy and pressure.

Example 2: Deriving the Fermi-Dirac Distribution

Problem: Derive the average occupation number $\langle n_i \rangle$ for fermions in state (i) at thermal equilibrium.

Solution:

- **Identify the statistical ensemble:** Grand canonical ensemble, since particle number can fluctuate.

- **Write the grand partition function Ξ :**

$$\Xi = \prod_i (1 + e^{-\beta(\epsilon_i - \mu)})$$

where ϵ_i is the energy of state (i) and μ is the chemical potential.

- **Calculate the average occupation number:**

$$\langle n_i \rangle = -\frac{1}{\beta} \frac{\partial \ln \Xi}{\partial \epsilon_i}$$

which simplifies to

$$\langle n_i \rangle = \frac{1}{e^{\beta(\epsilon_i - \mu)} + 1}$$

$$\langle n_i \rangle = \frac{1}{e^{\beta(\epsilon_i - \mu)} + 1}$$

\]

Result:

\[

\boxed{\

$$\langle n_i \rangle = \frac{1}{e^{\beta(\epsilon_i - \mu)} + 1}$$

}

\]

This is the Fermi-Dirac distribution, fundamental in understanding electronic properties of materials.
